stabilityFeedbackICB

Overview

This MATLAB Live Script is associated with the paper "Idiosyncratic choice bias and feedback-induced bias differ in their long-term dynamics".

All data files required to reproduce our results available in https://github.com/Lior-Lebovich/stabilityFeedbackICB.

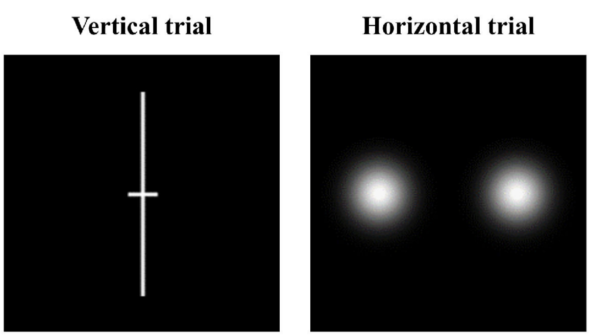
Contributor

This code was authored by Lior Lebovich, 2024.

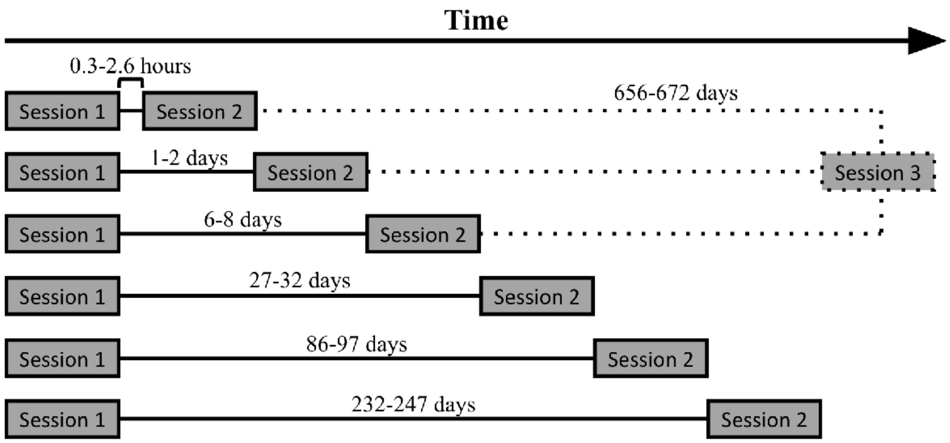
Datasets

This research includes two studies of Idiosyncratic Choice Biases (ICBs) in human participants.

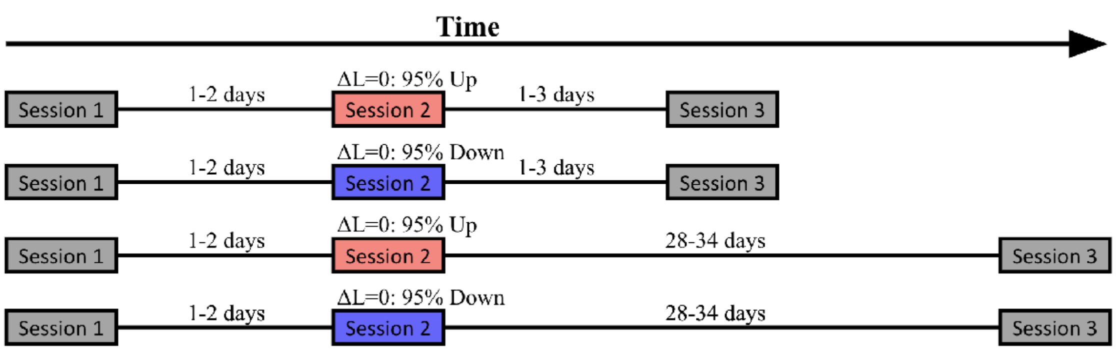
Each session consisted of 480 trials, 240 vertical and 240 horizontal. In a vertical trial, a vertical line, transected by a horizontal shorter line, was presented on a screen and participants were instructed to indicate which vertical segment out of two is longer. In a horizontal trial, two white Gaussian blur circles were presented on a black screen and participants were instructed to indicate which circle out of two is bigger. Trials in each session were ordered in 160 alternating blocks of 3 horizontal and 3 vertical transected lines. Unbeknown to the participants, there were 40 impossible vertical and 40 impossible horizontal trials in each session, appearing exclusively as first in a block of three trials. Stimuli in the possible trials were uniformly distributed, with an equal number of offsets in each direction.



Stability dataset: In the first study, participants' ICBs were measured in two repeated experimental sessions that were either 1 hour, 1 day, 1 week, 1 month, 3 months or 8 months apart. A subset of the participants also participated in a third session, 22 months after the second session. No trial-to-trial feedback was provided to participants. There were approx. 30 participants in each delay group.



Feedback dataset: In the second study, participants' ICBs were measured in three repeated experimental sessions. The first and second sessions were 1 day apart whereas the second and last sessions were either 1 day or 1 month apart. The first and last sessions were as in the sessions in the stability experiment, absent of trial-to-trial feedback, whereas the second session included trial-to-trial feedback. The trial-to-trial feedback was congruent with the stimuli in all possible trials (400/480 of the trials) and biased in the impossible trials (80/480 of the trials). The biased feedback considered one alternative as the correct response in 95% of the impossible trials and the other alternative as the correct response in 5% of the impossible trials. Participants were matched according to their ICBs in the first session and divided 8 groups: 2 second-last sessions delay times X 2 vertical feedback manipulation X 2 horizontal feedback manipulation.



Main data files:

Main data files are stored by dataset folders.

Response data of each delay group is stored under *[STUDY]/sortedTables/sortedTable_[STUDY]_[DELAY_GROUP].csv*.

Between-sessions hour differences for each delay group are stored under *[STUDY]/assignTables/assignTable_[STUDY]_[DELAY_GROUP].csv*.

Response data of the 8 months delay group in the stability study:

```
dataName = 'stability';
timeName = 'months8';
dataTable = readtable([dataName '/sortedTables/sortedTable_' ...
    dataName '_' timeName '.csv']);
```

```
head(dataTable, 8)
```

```

Read and process experimental data:

Define study (data), task, delay-group names and stimuli deviations:

```
dataNames = {'stability', 'feedback'};
taskNames = {'Vertical','Horizontal'};
dataTimeGroupNames.feedback = {'day','month'};
dataTimeGroupNames.stability = {'hour','day','week','month','months3',...
    'months8','years'};
dataTimeGroupNames2.stability = {'hour','day','week','month','3 months',...
    '8 months','22 months'};
dataTimeGroupNames2.feedback = dataTimeGroupNames.feedback;
timeStartName.stability = '';
timeStartName.feedback = 'time1';
relFields.stability = {'response'};
relFields.feedback = {'oldResponse','responseCongruent'};
nTrialsDevSessImp = 40;
nTrialsDevSessPos = 20;
devs.stability.Vertical = -10:2:10;
devs.feedback.Vertical = -10:2:10;
devs.stability.Horizontal = -10:2:10;
devs.feedback.Horizontal = -5:1:5;
```

```
toNormDev.Vertical = 100;
toNormDev.Horizontal = 75;
nTrialsVect = [20*ones(1,5), 40, 20*ones(1,5)];
xLab.Vertical = '\DeltaL/L';
xLab.Horizontal = '\DeltaR/R';
yLab.Vertical = 'p_{up}';
yLab.Horizontal = 'p_{right}';
save('behavioralDefs.mat');
```

Note that for the feedback data, the field 'oldResponse' denotes the actual respose (1=up/right and 0=down/left) whereas the field responseCongruent denotes whether the response is congruent(=1) or incungruent(=0) with the feedback manipulation.

Read, compute and store responses, response times and P for each study, delay group, session, task, participant, deviation and manipulation (for feedback data) and read 1st session's demographic data:

```
for dat = 1:length(dataNames)
    dataName = dataNames{dat};
    timeNames = dataTimeGroupNames.(dataName);
    % read demographic data (provided: 1st session onset):
    demogTable = readtable([dataName '/demogTable/demog_table_' ...
        dataName '.csv']);
    for ti = 1:length(timeNames)
        timeName = timeNames{ti};
        % read resposne data:
        assignTable = readtable([dataName '/assignTables/assignTable_' ...
            dataName '_' timeStartName.(dataName) timeName '.csv']);
        uniIDs = assignTable.ID;
        nSubs = length(uniIDs);
        dataTable = readtable([dataName '/sortedTables/sortedTable_' ...
            dataName '_' timeStartName.(dataName) timeName '.csv']);
        nSessS = max(unique(dataTable.session));

        for task = 1:length(taskNames)
            taskName = taskNames{task};
            % if feedback, then also read the manipulations:
            if strcmp(dataName,'feedback')
                behav.(dataName).(taskName).(timeName).manip = ...
                    assignTable.(['manip' taskName(1:3)]);
            end

            % save demographic data:
            age_cell = cell(nSubs, 1);
            gender_cell = cell(nSubs, 1);
            hand_cell = cell(nSubs, 1);
            for sub = 1:length(uniIDs)
                subID = uniIDs{sub};
                demogSub = demogTable( strcmp( demogTable.ID, subID ) , : );
                age_cell{sub} = demogSub.AgeYears;
                gender_cell{sub} = demogSub.Sex{1};
```

```
                hand_cell{sub} = demogSub.Hand{1};
            end
            behav.(dataName).(taskName).(timeName).demog.age = age_cell;
            behav.(dataName).(taskName).(timeName).demog.gender =
gender_cell;
            behav.(dataName).(taskName).(timeName).demog.hand = hand_cell;
            behav.(dataName).(taskName).(timeName).demog.ID = uniIDs;

            %
            for dev = devs.(dataName).(taskName)
                if dev == 0
                    nTrialsDev = nTrialsDevSessImp;

save('behavioralData.mat','behav');
```

Fig. 1 - stability - ICB in the first session:

Load processed data and definitions:

```
%load('behavioralDefs.mat');
%load('behavioralData.mat');
```

Compute performance in stability study:

Read stability data:

```
dat = 1;
dataName = dataNames{dat};
timeNames = dataTimeGroupNames.(dataName);
timeNames2 = dataTimeGroupNames2.(dataName);
for task = 1:length(taskNames)
    taskName = taskNames{task};
    lastPar = 0;
    pMat.(taskName) = nan(183,11);
    timeCell = cell(183,1);
    for ti = 1:length(timeNames)-1
        timeName = timeNames{ti};
        timeName2 = timeNames2{ti};
        nSubsTime = length( behav.(dataName).Vertical.(timeName ...
```

```
            ).sess1.dev0.response.mean );
        timeCell(lastPar+1:lastPar+nSubsTime) = {timeName2};
        DEV = devs.(dataName).(taskName);
        for d = 1:length(DEV)
            dev = DEV(d);
            if dev < 0
                devName = ['m' num2str(abs(dev))];
            else
                devName = num2str(dev);
            end
            pMat.(taskName)( lastPar+1:lastPar+nSubsTime, d ) = ...
                behav.(dataName).(taskName).(timeName).sess1.(...
                ['dev' devName]).response.mean;
        end
        lastPar = lastPar + nSubsTime;
    end
end
```

Compute performance in vertical task:

Note that performance is measured from possible trials (dev~=0) of the first session.

```
performanceVertical = 0.5 * ( 1 - mean( pMat.Vertical(:,1:5), 2 ) + ...
    mean( pMat.Vertical(:,7:11), 2 ) );
performanceVertical_avg = mean(100 * performanceVertical)
```

```
performanceVertical_avg = 92.0601
```

```
performanceVertical_std = std(100 * performanceVertical)
```

```
performanceVertical_std = 5.3114
```

```
performanceVertical_minmax = 100 * [min(performanceVertical), ...
    max(performanceVertical)]
```

```
performanceVertical_minmax = 1×2
   62.0000   99.5000
```

Compute performance in horizontal task:

```
performanceHorizontal = 0.5 * ( 1 - mean( pMat.Horizontal(:,1:5), 2 ) + ...
    mean( pMat.Horizontal(:,7:11), 2 ) );
performanceHorizontal_avg = mean(100 * performanceHorizontal)
```

```
performanceHorizontal_avg = 98.5738
```

```
performanceHorizontal_std = std(100 * performanceHorizontal)
```

```
performanceHorizontal_std = 1.7894
```

```
performanceHorizontal_minmax = 100 * [min(performanceHorizontal), ...
    max(performanceHorizontal)]
```

```
performanceHorizontal_minmax = 1×2
   89.5000  100.0000
```

Fig. 1A (&S4A): Psychometric curves of 3 example participants:

Note that different example participants were selected for the vertical and horizontal tasks.

```
% Define example participants for each task:

FUNCTIONS

This code uses 3 custom functions:

(1) runningWindow - see below

(2) psychometric - see below

(3) plotDiscreteViolin - see below

(3) myBinomTest - external. Reference: Matthew Nelson (2015). https://www.mathworks.com/matlabcentral/fileexchange/24813-mybinomtest-s-n-p-sided MATLAB Central File Exchange. Retrieved February 9, 2016.

psychometric

```
function [meanY,semY] = psychometric( data, xDeltaVector, flag, colVect )

% Creates a psychometric curve with mean+-SEM of the input matrix and plot
% the result by default. Element i,j is the mean of subject i in trial type
% j.
% NaN values are omitted.

% INPUT 1: data is N x M matrix, corresponding to data of N subjects,
% with M trial difficulty levels.
% INPUT 2: xDeltaVector is the difficulty level vector.
% INPUT 3 (optional): flag. 'on' (default) plots a corresponding figure.
% 'off' will not output a plot.
% INPUT 4 (optional): colVect. 1x3 color vect. The default is black.

% OUTPUT 1: meanY is the mean over subjects, for each difficulty.
% OUTPUT 2: semY is the standard error of the mean.

% compute the running window:
```

```
meanY = mean(data, 'omitnan');
semY = std(data, 'omitnan') ./ sqrt( sum(~isnan(data)) );

% plot the results:
if nargin == 2 || (nargin >= 3 && strcmp(flag,'on'))
    if nargin == 4
        col = colVect;
    else
        col = [0,0,0];
    end
    patch( [xDeltaVector, flip(xDeltaVector)], ...
        [meanY + semY, flip(meanY - semY)], ...
        col, 'EdgeColor', 'none', 'FaceAlpha', .3 );
    hold on;
    plot( xDeltaVector, meanY, 'Color', col, 'lineWidth', 1, 'Marker', '.'
);
    hold on;
end

end
```

runningWindow

```
function [meanInWin,semInWin,t] = runningWindow( data, winSize, flag, ...
    colVect )

% Creates a running window of mean+-SEM of the input matrix and plot the
% result by default, for consecutive winSize trials (e.g., 1:winSize-1,
% 2:winSize, ... M-winSize+1:M).
% NaN values are omitted.

% INPUT 1: data is N x M matrix, corresponding to data of N subjects,
% in M trials.
% INPUT 2: winSize is the window size.
% INPUT 3 (optional): flag. 'on' (default) plots a corresponding figure.
% 'off' will not output a plot.
% INPUT 4 (optional): colVect. 1x3 color vect. The default is black.

% OUTPUT 1: meanInWin is the mean in the window.
% OUTPUT 2: semInWin is the standard error of the mean in the window.
% OUTPUT 3: t is the average location of the window. Namely, the sum of the
% number of first plus last trials in the window, divided by 2.

% compute the running window:
nTrials = size(data,2);
meanInWin = nan(1,nTrials+1-winSize);
semInWin = nan(1,nTrials+1-winSize);
t = nan(1,nTrials+1-winSize);
for winStLoc = 1:(nTrials+1-winSize)
    winLocs = winStLoc:(winStLoc+winSize-1);
```

```
    winChoices = data(:,winLocs);
    p = mean( winChoices, 2, 'omitnan' );
    meanInWin(winStLoc) = mean( p, 'omitnan' );
    semInWin(winStLoc) = std( p, 'omitnan' ) / sqrt( sum(~isnan(p)) );
    t(winStLoc) = .5 * ( winLocs(1) + winLocs(end) );
end

% plot the results:
